37 **Abstract**

38 Cytolytic proteins and peptide toxins are classical virulence factors of several bacterial
39 pathogens which disrupt epithelial barrier function, damage cells and activate or modulate
40 host immune responses. Until now human pathogenic fungi were not known to possess such
41 toxins. Here we identify the first fungal cytolytic peptide toxin in the opportunistic pathogen
42 *Candida albicans*. This secreted toxin directly damages epithelial membranes, triggers a
43 danger response signalling pathway and activates epithelial immunity. Toxin-mediated
44 membrane permeabilization is enhanced by a positively charged C-terminus and triggers an
45 inward current concomitant with calcium influx. *C. albicans* strains lacking this toxin do not
46 activate or damage epithelial cells and are avirulent in animal models of mucosal infection.
47 We propose the name ‘Candidalysin’ for this cytolytic peptide toxin; a newly identified,
48 critical molecular determinant of epithelial damage and host recognition of the clinically
49 important fungus, *C. albicans*.

50

51

52 **Introduction**

53 The ability of mucosal surfaces to discriminate between commensal and pathogenic microbes
54 is essential to human health. The fungus *Candida albicans* is normally a benign member of
55 the human microbiota but is also responsible for millions of mucosal infections each year in
56 immunocompromised hosts, often with severe morbidity¹. A defining feature of *C. albicans*
57 pathogenesis is the transition from yeast to invasive filamentous hyphae². Hyphae damage
58 mucosal epithelia and induce activation of the activating protein-1 (AP-1) transcription factor
59 c-Fos (via p38-MAPK) and the MAPK phosphatase MKP1 (via ERK1/2-MAPK), which
60 trigger pro-inflammatory cytokine responses³⁻⁷. These signaling events constitute a ‘danger
61 response’ against invasive hyphae, thus serving as a sensor of pathogenic *C. albicans*
62 invasion⁸⁻¹⁴. However, it is unclear how *C. albicans* hyphae induce epithelial inflammatory
63 responses and cell damage during mucosal infections. Here we identify and characterize
64 Candidalysin, the first cytolytic peptide toxin isolated from any human fungal pathogen, as
65 the hyphal factor critical for epithelial immune activation and *C. albicans* mucosal infection.

66

67 **Ecelp is critical for epithelial activation and damage**

68 Despite the well-known association between filamentation and virulence, the molecular
69 mechanism underlying hypha-driven epithelial activation and mucosal damage has remained
70 obscure. To elucidate this mechanism, we screened a panel of *C. albicans* gene deletion

mutants that targeted key processes, pathways and proteins known or predicted to be associated with the yeast-hyphal transition and pathogenicity (62 strains). Only hypha-producing strains induced MKP1 phosphorylation (p-MKP1), c-Fos, cytokines (IL-1 α , IL-6, G-CSF) and damage in oral epithelial cells (Extended Data Table 1). However, one *C. albicans* mutant (*ece1* Δ/Δ)¹⁵ formed normal hyphae but was incapable of inducing these epithelial danger responses. *C. albicans* *ECE1* (extent of cell elongation) is highly expressed by hyphae during epithelial infection (Extended Data Fig. 1a, b) and is predicted to encode a secreted protein¹⁶. To probe its function we generated a panel of *C. albicans* *ECE1*-mutants (Extended Data Table 2). The *ece1* Δ/Δ strain formed normal hyphae on (Extended Data Fig. 1c), and adhered to and invaded human epithelial cells similarly to wild type *C. albicans* (Extended Data Fig. 1d, e). Indeed, *ece1* Δ/Δ was capable of extensive epithelial invasion, penetrating through multiple epithelial cells (Extended Data Fig. 1f). Despite this, invasive *ece1* Δ/Δ hyphae did not damage epithelia or induce p-MKP1/c-Fos mediated danger responses or cytokine secretion (Fig. 1a-d). Thus, Ece1p is critical for epithelial damage and innate recognition of *C. albicans* hyphae *in vitro*.

86

87 **Ece1p is critical for mucosal pathogenesis**

We next assessed the role of *ECE1* in two *in vivo* models of *C. albicans* mucosal infection. In murine oropharyngeal candidiasis (OPC)¹⁷, mice infected with *C. albicans* wild type or *ECE1* re-integrand (*ece1* Δ/Δ +*ECE1*) strains exhibited disease symptoms, including extensive hyphal invasion of the tongue epithelium, micro-abscesses of infiltrating neutrophils and tissue damage (Fig. 1e, f, h, i). In contrast, tongue tissue from *ece1* Δ/Δ -infected animals (n = 17/20) showed no invasive fungi and no inflammatory infiltrates or damage (Fig. 1g). We detected very low numbers of *ece1* Δ/Δ cells in only 3/20 mice (Extended Data Fig. 2a), which showed no evidence of local epithelial damage (not shown). Quantification of histology sections indicated that the percentage of epithelial surface infected was significantly greater with the wild type and *ECE1* re-integrand strains (Extended Data Fig. 2b). In a zebrafish swimbladder model of mucosal infection^{18,19}, neutrophil recruitment and tissue damage were both significantly lower following *ece1* Δ/Δ infection as compared with the wild type strain (Fig. 1j, k, Extended Data Fig. 2c, d). Therefore, *C. albicans* Ece1p is critical for mucosal pathogenesis and is an innate immune activator *in vivo*.

102

103 **Ece1p encodes a cytolytic peptide toxin**

Ece1p is an *in vitro* substrate for Kex2p, a Golgi-located protease that cleaves proteins after lysine-arginine (KR) motifs²⁰. Ece1p contains seven KR-processing sites, suggesting it has the potential to produce eight secreted peptides from *C. albicans*²⁰ (Extended Data Fig. 3a, b). Liquid chromatography – tandem mass spectrometry (LC-MS/MS) analysis confirmed that recombinant Kex2p (rKex2p) processes recombinant Ece1p (rEce1p) and that all eight peptides generated terminated in KR (and fragments thereof, showing that less efficient processing occurs also after a single K or R) (Supplementary information). The importance of Kex2p-mediated Ece1p processing was demonstrated using a *kex2Δ/Δ* null strain²¹, which was unable to damage oral epithelia or induce p-MKP1/c-Fos mediated danger responses or cytokine secretion (Extended Data Table 1). To determine which Ece1p peptide(s) were responsible for epithelial activation and damage, oral epithelial cells were incubated with peptides Ece1-I-VIII (1.5 – 70 μM). Only Ece1-III₆₂₋₉₃ induced p-MKP1, c-Fos, cytokines and damage (Fig. 2a-c, Extended Data Fig. 3c-e). Notably, low Ece1-III₆₂₋₉₃ concentrations (1.5 – 15 μM) were sufficient to induce c-Fos DNA binding (Fig. 2d), G-CSF and GM-CSF (Fig. 2c, Extended Data Fig. 3c), while high Ece1-III₆₂₋₉₃ concentrations (70 μM) were required to induce damage (Fig. 2e) and the damage-associated cytokines IL-1α and IL-6, respectively (Extended Data Fig. 3d, e). Ece1-III₆₂₋₉₃ could also directly lyse multiple human epithelial cell types and induce hemolysis of red blood cells, a classical test for cytotoxin activity (not shown). Neither the N-terminal hydrophobic region (Ece1-III₆₂₋₈₅) nor the C-terminal hydrophilic region (Ece1-III₈₆₋₉₃) induced p-MKP1, c-Fos, cytokines or damage of epithelial cells, either individually or in combination (Extended Data Fig. 3f-h), demonstrating that the peptide containing both regions is required for activity. Therefore, Ece1-III₆₂₋₉₃ is the active region of Ece1p, acting as an epithelial immune activator and a cytolytic agent.

To confirm that Ece1-III₆₂₋₉₃ drives epithelial activation and fungal pathogenicity, we generated a *C. albicans* strain lacking only the Ece1-III₆₂₋₉₃ region (*ece1Δ/Δ+ECE1_{Δ184-279}*). LC-MS/MS analysis showed that the modified protein in this strain is stable, secreted, and processed into each of the predicted peptide fragments, with the exception of the deleted peptide toxin (Supplementary information). Like *ece1Δ/Δ*, *ece1Δ/Δ+ECE1_{Δ184-279}* efficiently formed invasive hyphae (not shown). However, *ece1Δ/Δ+ECE1_{Δ184-279}* was unable to induce p-MKP1, c-Fos DNA binding, cytokines, or damage epithelia (Fig. 2f-i). In murine OPC, unlike the *ece1Δ/Δ+ECE1* complemented strain, *ece1Δ/Δ+ECE1_{Δ184-279}*-infected mice demonstrated absent (n = 4/10) or low (n = 6/10) fungal burdens, with no evidence of inflammatory infiltrates or local epithelial damage (Fig. 2j-l, Extended Data Fig. 4a and 4b).

Likewise, *ece1* Δ/Δ +*ECE1*_{Δ184-279} did not induce full damage in the zebrafish swimbladder model (Fig. 2m, Extended Data Fig. 4c). In contrast, injection of lytic doses of Ece1-III₆₂₋₉₃ into the swimbladder induced epithelial damage (Fig. 2n, o). Thus, Ece1-III₆₂₋₉₃ is both necessary and sufficient for epithelial immune activation, damage and mucosal infection *in vivo*. The amphipathic properties of Ece1-III₆₂₋₉₃ (SIIGIIMGILGNIPQVIQIIMSIVKAFKGNKR) coupled with the α -helical structure of the N-terminal hydrophobic region (Extended Data Fig. 5a, b) indicated that this fungal peptide may act similarly to cationic antimicrobial peptides and peptide toxins such as melittin²² (honey bee), magainin²³ (African clawed frog) and alamethicin²⁴ (*Trichoderma viride*). Cytolytic peptide toxins have not previously been found in human pathogenic fungi but bacterial cytolytic toxins are known to induce lesions after binding to target cell membranes^{25,26}. To investigate the importance of lipid composition for Ece1-III₆₂₋₉₃-mediated cytolysis, we used Förster resonance energy transfer (FRET) and electrical impedance spectroscopy to analyze the interactions of Ece1-III₆₂₋₉₃ with model membranes comprised of lipid bilayers of dioleoylphosphatidylcholine (DOPC) with or without cholesterol. While Ece1-III₆₂₋₉₃ was able to efficiently intercalate into and permeabilize DOPC membranes, Ece1-III₆₂₋₉₃ permeabilization was enhanced in the presence of cholesterol (Fig. 3a, Extended Data Fig. 5c). Ece1-III₆₂₋₉₃-induced lesions were heterogeneous and transient (Extended Data Fig. 5d), indicating that the peptide may damage target membranes through a ‘carpet-like’ mechanism²⁷. Patch-clamp analysis of epithelial cells demonstrated that lesion formation by Ece1-III₆₂₋₉₃ is rapid and causes an inward current (Fig. 3b), associated with calcium influx (Fig. 3c). Similar phenomena occur with bacterial cytolytic toxins, which are known to trigger cell activation^{25,26,28}.

We postulated that the positively-charged C-terminal KR residues of Ece1-III₆₂₋₉₃ might be critical for interacting with negatively-charged components of host membranes to promote lesion formation. Substitution of the KR motif to AA (alanine-alanine; Ece1-III₆₂₋₉₃AA) did not affect membrane intercalation (not shown) but significantly reduced the peptide’s ability to permeabilize membranes, damage epithelial cells and induce calcium influx (Fig. 3c-e). Thus, the positive C-terminus of Ece1-III₆₂₋₉₃ is critical for lesion formation and damage induction in epithelial membranes. Notably, Ece1-III₆₂₋₉₃AA still induced p-MKP1, c-Fos and the non-damage associated cytokine G-CSF (Fig. 3f, g) but not the damage-associated cytokine IL-1 α (Fig. 3h), suggesting that Ece1-III₆₂₋₉₃AA can be recognized by epithelial immunity without damaging cells. This finding is important as it means that epithelial cells are not only responding to damage but have evolved to specifically recognise the peptide.

Ece1-III_{62-92K} is a secreted cytolytic peptide toxin

To demonstrate that Ece1-III is generated during epithelial infection, we performed LC-MS/MS analysis on the secretome from wild-type *C. albicans* hyphae grown in the presence and absence of epithelial cells (Supplementary information). Notably, Ece1-III was the only peptide detected in the presence of epithelial cells, indicating that the fungus secretes this toxin during mucosal infection. However, the predominant form of secreted Ece1-III terminated in a K residue (SIIGIIMGILGNIPQVIQIIMSIVKAFKGNK; Ece1-III_{62-92K}) and not KR (SIIGIIMGILGNIPQVIQIIMSIVKAFKGNKR; Ece1-III_{62-93KR}) (Extended Data Table 3). In fungi, it is known that following Kex2p processing, many proteins are subsequently cleaved by Kex1p²⁹ (also in the Golgi), removing the C-terminal R. LC-MS/MS analysis on the hyphal secretome of a *kex1Δ/Δ* mutant demonstrated that the predominant peptide secreted terminates in KR (not K) (Supplementary information). Therefore, Ece1p is also subject to ordered Kex2p/Kex1p processing. Accordingly, we confirmed that Ece1-III_{62-92K} functioned similarly to Ece1-III_{62-93KR} with respect to epithelial cell activation. Specifically, Ece1-III_{62-92K} is also α -helical (not shown) and induces c-Fos, p-MKP1, cytokines (IL-1 α , G-CSF), damage (LDH), membrane intercalation and permeabilization, and calcium influx (Fig 4a-g). Thus, the dominant peptide secreted from *C. albicans* hyphae during mucosal infection is Ece1-III_{62-92K}, which acts as a cytolytic peptide toxin that activates epithelial cells.

Based on these data, we propose a model of *C. albicans* mucosal infection whereby invasive hyphae secrete Ece1-III_{62-92K} into a membrane-bound ‘invasion pocket’^{30,31}, facilitating peptide accumulation (Extended Data Fig 6). During early stages of infection, sub-lytic concentrations of Ece1-III_{62-92K} induce epithelial immunity by activating the ‘danger response’ pathway (p-MKP1/c-Fos), alerting the host to the transition from colonizing yeast to invasive, toxin-producing hyphae. As infection progresses, Ece1-III_{62-92K} levels accumulate and elicit direct tissue damage. Mechanistically, we propose that the asymmetric distribution of charge along the α -helix of Ece1-III_{62-92K} facilitates correct peptide orientation relative to the host membrane, enabling intercalation, permeabilization and calcium influx. In conclusion, our data identifies *C. albicans* Ece1-III_{62-92K} as the first cytolytic peptide toxin in a human fungal pathogen and reveals the molecular mechanisms of epithelial damage and host recognition of this clinically important fungus. We propose the name ‘Candidalysin’ for this newly discovered fungal toxin.

(MOI = 0.01). **(e-i)** PAS-stained tongues from mice subjected to OPC 2 d p.i. **(e, g, h)** Whole-mount (x25) and **(f, i)** high-power (x200) views of PAS-stained tongues of mice infected with *C. albicans* wild type **(e, f)**, *ece1* Δ/Δ **(g)** and *ece1* Δ/Δ +*ECE1* **(h, i)**. Invading hyphae (black arrow) and inflammatory cells (blue arrow) are indicated. **(j)** Quantification of neutrophils in zebrafish swimbladder following infection with WT *C. albicans* (n (number of fish) = 47), *ece1* Δ/Δ (n = 53) or PBS (n = 40). **(k)** Quantification of damaged cells in zebrafish swimbladder after infection with *C. albicans* WT (n = 73), *ece1* Δ/Δ (n = 59) or vehicle (n = 63). Data are representative **(b, e-i)** or the mean **(a, c-d, j-k)** of three biological replicates. Error bars \pm SEM. Data were analyzed by one-way ANOVA **(a, d)**, paired T test **(c)** or Kruskal-Wallis **(j, k)** and * = $P < 0.05$, ** = $P < 0.01$, *** = $P < 0.001$. For gel source data, see Supplementary Figure 1.

Figure 2| *Ece1*-III₆₂₋₉₃ is the active region of *Ecelp* and is required for TR146 cell activation and mucosal *C. albicans* infection. **(a)** Induction of p-MKP-1 and c-Fos 2 h post-stimulation (p.s.) with *Ece1* peptides at 1.5 μ M. **(b)** LDH release 24 h p.s. with 70 μ M *Ece1* peptides. **(c)** Induction of G-CSF 24 h p.s. of with *Ece1*-III₆₂₋₉₃. **(d)** c-Fos DNA binding induction 3 h p.s. with sub-lytic concentrations of *Ece1*-III₆₂₋₉₃. **(e)** LDH release 24 h p.s. with *Ece1*-III₆₂₋₉₃. **(f)** Induction of p-MKP-1 and c-Fos 2 h post-infection (p.i.) with the indicated *C. albicans* strains (MOI = 10). **(g)** c-Fos DNA binding induction 3 h p.i. with indicated *C. albicans* strains (MOI = 10). **(h)** G-CSF secretion 24 h p.i. with indicated *C. albicans* strains (MOI = 0.01). **(i)** LDH release 24 h p.i. with indicated *C. albicans* strains (MOI = 0.01). **(j-l)** PAS stained tongue sections from mice subjected to OPC, 2 d p.i. with **(j, k)** *C. albicans ece1* Δ/Δ +*ECE1* (x25 and x200) or **(l)** *ece1* Δ/Δ +*ECE1* _{Δ 184-279}. Invading hyphae (black arrows) and infiltrating inflammatory cells (blue arrow) are shown. **(m)** Damaged cells in a zebrafish swimbladder 24 h p.i. with *C. albicans ece1* Δ/Δ +*ECE1* (n (number of fish) = 44), *ece1* Δ/Δ +*ECE1* _{Δ 184-279} (n = 58) or vehicle (n = 58). **(n)** Damaged cells in zebrafish swimbladders after stimulation with 9 ng (n = 51) or 1.25 ng (n = 56) *Ece1*-III₆₂₋₉₃, or vehicle (40% DMSO, n = 54 and 5% DMSO, n = 55). **(o)** Co-localization of adherens junctions (α -

catenin-citrine) with Ece1-III₆₂₋₉₃-damaged cells (Sytox Orange-positive cells) in a zebrafish swimbladder. Data are representative (**a, f, j-l, o**) or mean (**b-e, g-i, m-n**) of three biological replicates (**a-m**) or ten fish (**o**). Error bars show \pm SEM. Data were analyzed by one-way ANOVA (**b, c, e, h, i**) paired T test (**d, g**) or Kruskal-Wallis (**m,n**). * = $P < 0.05$, ** = $P < 0.01$, *** = $P < 0.001$ (compared with vehicle control unless otherwise indicated). For gel source data, see Supplementary Figure 1.

Figure 3| Ece1-III₆₂₋₉₃ functions as a cytolytic peptide toxin. (**a**) Kinetic changes in conductance of tethered lipid membranes after exposure to different concentrations of Ece1-III₆₂₋₉₃. (**b**) Evoked inward current at a membrane potential of -60 mV in TR146 cells post-addition of Ece1-III₆₂₋₉₃ or ionomycin (positive control); individual (representative) and cumulative changes (bar chart - number of cells analysed below each bar) shown. (**c**) Intracellular calcium level kinetics in TR146 cells post-stimulation (p.s.) with Ece1-III₆₂₋₉₃ wild type (Ece1-III_{62-93KR}) or Ece1-III₆₂₋₉₃ AA C-terminal substitution (Ece1-III_{62-93AA}). (**d**) Kinetic changes in conductance of tethered DOPC membranes after exposure to different concentrations of Ece1-III₆₂₋₉₃. (**e**) LDH release from TR146 cells 24 h p.s. with Ece1-III_{62-93KR} or Ece1-III_{62-93AA}. (**f**) Induction of p-MKP-1 and c-Fos 2 h in TR146 cells p.s. with Ece1-III_{62-93KR} or Ece1-III_{62-93AA}. Secretion of (**g**) G-CSF and (**h**) IL-1 α from TR146 cells 24 h p.s. with Ece1-III_{62-93KR} or Ece1-III_{62-93AA}. Data shown are representative (**a, d, f**) or mean (**b-c, e, g-h**) of three biological replicates. Error bars show \pm SEM. Data were analyzed by one-way ANOVA (**e, g** and **f**) and * = $P < 0.05$, ** = $P < 0.01$, *** = $P < 0.001$. For gel source data, see Supplementary Figure 1.

Figure 4| Ece1-III_{62-92K} functions as a cytolytic peptide toxin that activates and damages epithelial cells. (**a**) Induction of p-MKP-1 and c-Fos 2 h post-stimulation (p.s.), and (**b**) secretion of G-CSF and IL-1- α 24 h p.s., and (**c**) LDH release 24 h p.s. of TR146 cells with Ece1-III_{62-92K}. (**d**) Förster resonance energy transfer (FRET) showing intercalation of Ece1-III_{62-92K} (10 μ M) into lipid liposomes. (**e**) Average peptide concentration-dependent changes in conductance of tethered lipid membranes. (**f**) Ece1-III_{62-92K} (4 μ M) induced permeabilization of planar lipid membranes showing heterogeneous and transient lesions leading to membrane rupture. (**g**) Intracellular calcium level kinetics in TR146 cells p.s. with Ece1-III_{62-92K}. Data shown are representative (**a, d, f**) or mean (**b-c, e, g**) of three biological replicates. Error bars show \pm SEM. Data are analyzed by one-way ANOVA (**b, c**). * = $P <$

0.05, ** = $P < 0.01$, *** = $P < 0.001$ (compared with vehicle control). For gel source data, see Supplementary Figure 1.

Extended Data Figure legends

Extended Data Figure 1| *C. albicans* *ECE1* expression and phenotypic effects of *ECE1* gene deletion. (a) Relative expression (vs $t = 0$) of *ECE1* in *C. albicans* wild type over time after addition of yeast cells to TR146 epithelial cells as measured by RT-qPCR. (b) Imaging confirmation of *ECE1* expression over time within *C. albicans* wild type. *C. albicans* cells expressing GFP under the control of the *ECE1* 5' intragenic region, containing the *ECE1* promoter, were grown on TR146 epithelial cells and stained with calcofluor white (CFW, post-permeabilization) to show cell wall chitin and Alexa-Fluor-647-labelled concanavalin A (ConA, pre-permeabilization) to show carbohydrates. A composite image showing CFW, ConA, GFP and the brightfield (BF) image is shown. (c) Scanning electron micrographs (top panels, 5 h) and light microscopy (bottom panels, 24 h) showing no gross abnormalities in hypha formation between *C. albicans* wild type (BWP17+CIp30), *ECE1*-deletion (*ece1Δ/Δ*) and *ECE1* re-integrand (*ece1Δ/Δ+ECE1*) strains after infection of TR146 epithelial cells. (d) No difference in adhesion of *C. albicans* wild type, *ece1Δ/Δ* and *ece1Δ/Δ+ECE1* strains to TR146 epithelial cells after 60 min. (e) No difference in invasion of *C. albicans* wild type, *ece1Δ/Δ* and *ece1Δ/Δ+ECE1* strains into TR146 epithelial cells after 3 h. (f) Fluorescence staining of *C. albicans* wild type and *ece1Δ/Δ* hyphae invading through TR146 epithelial cells. Fungal cells are stained with calcofluor white (CFW, post-permeabilization) and Alexa-Fluor-647-labelled concanavalin A (ConA, pre-permeabilization) to show cell wall chitin and carbohydrates, respectively, and to distinguish between invading hyphae (only stained after permeabilization) and non-invading hyphae (stained both pre- and post-permeabilization). Levels of chitin and β -glucan are comparable in both strains. White arrows indicate invasion into epithelial cells. Data shown are representative (b, c, f) or the mean (a, d, e) of three biological replicates. Error bars show \pm SEM.

Extended Data Figure 2| *C. albicans* Ece1p is critical for mucosal virulence *in vivo*. (a) Fungal burdens recovered from the tongues of mice infected with *C. albicans* wild type (BWP17+CIp30) ($n = 13$), *ECE1*-deletion (*ece1Δ/Δ*) (n (number of mice) = 20) and *ECE1* re-integrand (*ece1Δ/Δ+ECE1*) ($n = 24$) strains after 2 day oropharyngeal infection. (b) Average

percentage of the entire tongue epithelium area infected in different groups of mice infected with the different *C. albicans* strains. **(c)** Confocal imaging of 4 day post-fertilization (dpf) *mpo-gfp* transgenic zebrafish swimbladders infected with *C. albicans* wild type (BWP17+CIp30+*dTomato*), *ECE1*-deletion (*ece1Δ/Δ*+*dTomato*) and *ECE1* re-integrand (*ece1Δ/Δ*+*ECE1*+*dTomato*) strains for 24 h. *C. albicans* cells appear red whilst neutrophils appear green. Red dots outline the swimbladder. Images are composites of maximum projections in the red and green channels (25 slices each, approximately 100 μm depth) with (left) or without (right) a single slice in the DIC channel overlay. Scale bars represent 100 μm. **(d)** Confocal imaging of 4 dpf zebrafish swimbladders infected with *C. albicans* wild type (BWP17+CIp30+*dTomato*), *ECE1*-deletion (*ece1Δ/Δ*+*dTomato*) and *ECE1* re-integrand (*ece1Δ/Δ*+*ECE1*+*dTomato*) strains for 24 h stained with the fluorescent exclusion dye Sytox Green. *C. albicans* cells appear red and damaged epithelial cells appear green. White dots outline the pronephros and red dots outline the swimbladder. Images are composites of maximum projections in the red and green channels (25 slices each, approximately 100 μm depth) with (left) or without (right) a single slice in the DIC channel overlay. High magnification images of the white boxes are shown. Scale bars (bottom right) represent 100 μm (low magnification) and 30 μm (high magnification). Data shown are the mean **(a, b)** or representative **(c, d)** of at least three biological replicates. Error bars show ± SEM. Data were analyzed by Mann-Whitney test. *** = $P < 0.001$.

Extended Data Figure 3| Ece1-III₆₂₋₉₃ is the active region of Ece1p. **(a)** Amino acid sequence of Ece1p and a schematic of the protein, indicating the signal peptide (SP), lysine-arginine motifs (KR) at the C-terminus of each peptide, and the processed peptides (Ece1-I-VIII) produced by Kex2p cleavage. **(b)** Amino acid sequences of the processed peptides (Ece1-I-VIII) produced by Kex2p cleavage. Induction of **(c)** GM-CSF, **(d)** IL-1α and **(e)** IL-6 secreted after stimulation of TR146 epithelial cells for 24 h with varying concentrations of Ece1-III₆₂₋₉₃ (70 μM - 1.5 μM). **(f)** Phosphorylation of MKP-1 and c-Fos production after 2 h treatment of TR146 epithelial cells with 15 μM of Ece1-III₆₂₋₈₅ (hydrophobic region), Ece1-III₈₆₋₉₃ (hydrophilic region), Ece1-III₆₂₋₈₅ and Ece1-III₈₆₋₉₃ together, or Ece1-III₆₂₋₉₃ alone. **(g)** Induction of G-CSF secretion after 24 h treatment of TR146 epithelial cells with 15 μM of Ece1-III₆₂₋₈₅, Ece1-III₈₆₋₉₃, Ece1-III₆₂₋₈₅ and Ece1-III₈₆₋₉₃ together, or Ece1-III₆₂₋₉₃ alone. **(h)** Fold change induction of LDH release after 24 h treatment of TR146 epithelial cells with 70 μM of Ece1-III₆₂₋₈₅, Ece1-III₈₆₋₉₃, Ece1-III₆₂₋₈₅ and Ece1-III₈₆₋₉₃ together, or Ece1-III₆₂₋₉₃ alone. Data shown are representative **(f)** or the mean **(c-e, g-h)** of three biological replicates.

Error bars show \pm SEM. Data were analyzed by one-way ANOVA. * = $P < 0.05$, ** = $P < 0.01$, *** = $P < 0.001$ (compared with vehicle control). For gel source data, see Supplementary Figure 1.

Extended Data Figure 4| Ece1-III₆₂₋₉₃ is required for *C. albicans* mucosal infection. (a)

Fungal burdens recovered from the tongues of mice infected with *C. albicans* wild type (BWP17+CIp30) (n = 13), *ECE1*-deletion (*ece1 Δ /* Δ) (n = 20), *ECE1* re-integrand (*ece1 Δ /* Δ +*ECE1*) (n = 24) and Ece1-III₆₂₋₉₃ deletion (*ece1 Δ /* Δ +*ECE1* _{Δ 184-279}) (n = 10) strains after 2 day oropharyngeal infection. (b) Average percentage of the entire tongue epithelium area infected in different groups of mice infected with the different *C. albicans* strains. (c) Confocal imaging of 4 dpf zebrafish swimbladders infected with *C. albicans* Ece1-III₆₂₋₉₃ deletion (*ece1 Δ /* Δ +*ECE1* _{Δ 184-279}+*dTomato*) and *ECE1* re-integrand (*ece1 Δ /* Δ +*ECE1*+*dTomato*) strains for 24 h stained with the fluorescent exclusion dye Sytox Green. *C. albicans* cells appear red and damaged cells appear green. White dots outline the pronephros and red dots outline the swimbladder. Images are composites of maximum projections in the red and green channels (25 slices each, approximately 100 μ m depth) with (left) or without (right) a single slice in the DIC channel overlay. Scale bars (bottom right) represent 100 μ m. Data shown are the mean (a) or representative (b, c) of at least three biological replicates. Error bars show \pm SEM. Data were analyzed by Mann-Whitney test. ** = $P < 0.01$, *** = $P < 0.001$.

Extended Data Figure 5| Ece1-III₆₂₋₉₃ is a cytolytic α -helical peptide. (a)

Circular dichroism spectra showing the α -helical conformation of Ece1-III₆₂₋₉₃ in buffer (100 mM KCl, 5 mM HEPES, pH 7). Increasing the temperature from 25°C to 40°C did not affect the stability of the α -helical structure. (b) Diagram to illustrate the amphipathic nature of Ece1-III₆₂₋₉₃ (residues 62-78, left panel; residues 79-93, right panel). Residues with hydrophobic or polar/charged side chains are displayed with a blue and white background, respectively. Modified from output generated in PEPWHEEL (<http://emboss.bioinformatics.nl/cgi-bin/emboss/pepwheel>). (c) Förster resonance energy transfer (FRET) experiments show the intercalation of Ece1-III₆₂₋₉₃ into lipid liposomes (10 μ M) composed of DOPC in the absence or presence of cholesterol. Peptide titration of Ece1-III₆₂₋₉₃ to liposomes showed slightly enhanced intercalation for pure DOPC. (d) Ece1-III₆₂₋₉₃ induced the permeabilization of planar lipid membranes composed of DOPC. The graph shows heterogeneous and transient

lesions leading finally to a rupture of the membrane. Ece1-III₆₂₋₉₃ concentration was 0.125 μ M. Data shown are representative of at least three biological replicates.

Extended Data Figure 6| Schematic of the role of Ece1-III in *C. albicans* infection of epithelial cells. During early stage infection of the mucosal surface by *C. albicans*, Ece1-III (red α -helix) is secreted into the invasion pocket created by the invading hypha (**a**). Sub-lytic concentrations of Ece1-III trigger epithelial signal transduction through MAPK, p38/MKP-1 and c-Fos (**b**) resulting in the production of immune regulatory cytokines (**c**). As the severity of the infection increases, Ece1-III accumulates (**d**) and once lytic concentrations are reached, causes membrane damage and the release of lactate dehydrogenase from the host epithelium (**e**), concomitant with calcium influx (**f**). Epithelial signal transduction is maintained (**g**) and additionally induces the release of damage associated cytokines, such as IL-1 α (**h**). Ece1-III may also have activity on the epithelial surface outside of the invasion pocket and on neighbouring cells not in contact with hyphae if Ece1-III is produced in sufficient concentrations.

METHODS

Cell lines, reagents and *Candida* strains

Experiments were carried out using the TR146 buccal epithelial squamous cell carcinoma line³² obtained from the European Collection of Authenticated Cell Cultures (ECACC) and grown in Dulbecco's Modified Eagle's Medium (DMEM, Sigma-Aldrich) supplemented with 10% fetal bovine serum (FBS) and 1% penicillin-streptomycin. Cells were routinely tested for mycoplasma contamination using mycoplasma-specific primers and were found to be negative. Prior to stimulation, confluent TR146 cells were serum-starved overnight, and all experiments were carried out in serum-free DMEM. *C. albicans* wild type strains included the autotrophic strain BWP17+CIp30³³ and the parental strain SC5314³⁴. Other *C. albicans* strains used and their sources are listed in Extended Data Tables 1 and 2. *C. albicans* cultures were grown in YPD medium (1% yeast extract, 2% peptone, 2% dextrose) at 30°C overnight. Cultures were washed in sterile PBS and adjusted to the required cell density. Antibodies to phospho-MKP1 and c-Fos were from Cell Signalling Technologies (New England Biolabs UK), mouse anti-human α -actin was from Millipore (UK), and goat anti-mouse and anti-rabbit horseradish peroxidase (HRP)-conjugated antibodies were from Jackson Immunologicals Ltd (Strattech Scientific, UK). Ece1p peptides were synthesized commercially (Proteogenix (France) or Peptide Synthetics (UK)).

Generation of *C. albicans* *ECE1* mutant strains

ECE1 deletion was performed as previously described³⁵. Deletion cassettes were generated by PCR³⁶. Primers ECE1-FG and ECE1-RG were used to amplify pFA-HIS1 and pFA-ARG4-based markers. *C. albicans* BWP17³⁷, was sequentially transformed³⁸ with the *ECE1*-HIS1 and *ECE1*-ARG4 deletion cassettes and then transformed with CIp10³⁹, yielding the *ece1* Δ/Δ deletion strain. For complementation, the *ECE1* gene plus upstream and downstream intergenic regions were amplified with primers ECE1-RecF3k and ECE1-RecR and cloned into plasmid CIp10 at *MluI* and *SalI* sites. This plasmid was transformed into the uridine auxotrophic *ece1* Δ/Δ strain, yielding the *ece1* Δ/Δ +*ECE1* complemented strain. For generation of the *ece1* Δ/Δ +*ECE1* _{Δ 184-279} strain, the CIp10-*ECE1* was amplified with primers Pep3-F1 and Pep3-R1, digested with *ClaI* and re-ligated, yielding the CIp10+*ECE1* _{Δ 184-279} plasmid. This plasmid was transformed into the uridine auxotrophic *ece1* Δ/Δ strain, yielding the *ece1* Δ/Δ +*ECE1* _{Δ 184-279} strain. All integrations were confirmed by PCR/sequencing and at least two independent isogenic transformants were created to confirm results. *KEX1* deletion

was performed exactly as the *ECE1* deletion but using primers KEX1-FG and KEX1-RG for creating the deletion cassette. Fluorescent strains of *ece1*Δ/Δ and BWP17 were constructed as previously described⁴⁰. Briefly, the *ece1*Δ/Δ and BWP17 strains were transformed with the pENO1-dTom-NATr plasmid. Primers used to clone and construct the *ECE1* genes and intragenic regions are listed in Extended Data Table 4. Strains are listed in Extended Data Table 2.

Construction of *C. albicans* *ECE1* promoter-GFP strain

ECE1 promoter (primers 5'*ECE1*prom-NarI / 3'*ECE1*prom-XhoI) and terminator (5'*ECE1*term-SacII / 5'*ECE1*term-SacI) were amplified and cloned into pADH1-GFP. Resulting pSK-p*ECE1*-GFP was verified by sequencing. *C. albicans* SC5314 was transformed with the p*ECE1*-GFP transformation cassette³⁸. Resistance to nourseothricin was used as selective marker and correct integration of GFP into the *ECE1* locus was verified by PCR. Primers for cloning and validation are listed in Extended Data Table 4. Strains are listed in Extended Data Table 2.

RNA isolation and real-time PCR analysis

C. albicans cells grown on TR146 epithelial cells were collected into RNA pure (PeqLab), centrifuged and the pellet resuspended in 400 μl AE buffer (50 mM Na-acetate pH 5.3, 10 mM EDTA, 1% SDS). Samples were vortexed (30 s), and an equal volume of phenol/chloroform/isoamyl alcohol (25:24:1) was added and incubated for 5 min (65°C) before subjected to 2x freeze-thawing. Lysates were clarified by centrifugation and the RNA precipitated with isopropyl alcohol/0.3 M sodium acetate by incubating for 1 h at -20°C. Precipitated pellets were washed (2x 1 ml 70% ice-cold ethanol), resuspended in DEPC-treated water and stored at -80°C. RNA integrity and concentration was confirmed using a Bioanalyzer (Agilent). RNA (500 ng) was treated with DNase (Epicenter) and cDNA synthesized using Reverse Transcriptase Superscript III (Invitrogen). cDNA samples were used for qPCR with EVAgreen mix (Bio&Sell). Primers (ACT1-F and ACT1-R for actin, ECE1-F and ECE1-R for *ECE1* - Extended Data Table 4) were used at a final concentration of 500 nM. qPCR amplifications were performed using a Biorad CFX96 thermocycler. Data was evaluated using Bio-Rad CFX Manager 3.1 (Bio-Rad) with *ACT1* as the reference gene and *t*₀ as the control sample.

Western blotting

TR146 cells were lysed using a modified RIPA lysis buffer (50 mM Tris-HCl pH 7.4, 150 mM NaCl, 1 mM EDTA, 1% Triton X-100, 1% sodium deoxycholate, 0.1% SDS) containing protease (Sigma-Aldrich) and phosphatase (Perbio Science) inhibitors⁴¹, left on ice (30 min) and then clarified (10 min) in a refrigerated microfuge. Lysate total protein content was determined using the BCA protein quantitation kit (Perbio Science). 20 µg of total protein was separated on 12% SDS-PAGE gels before transfer to nitrocellulose membranes (GE Healthcare). After probing with primary (1:1000) and secondary (1:10,000) antibodies, membranes were developed using Immobilon chemiluminescent substrate (Millipore) and exposed to X-Ray film (Fuji film). Human α -actin was used as a loading control.

Transcription factor DNA binding assay

DNA binding activity of transcription factors was assessed using the TransAM transcription factor ELISA system (Active Motif) as previously described^{41,42}. Serum-starved TR146 epithelial cells were treated for 3 h before being differentially lysed to recover nuclear proteins using a nuclear protein extraction kit (Active Motif) according to the manufacturer's protocol. Protein concentration was determined (BCA protein quantitation kit (Perbio Science)) and 5 µg of nuclear extract was assayed in the TransAM system according to the manufacturer's protocol. Data was expressed as fold-change in $A_{450\text{nm}}$ relative to resting cells.

Cytokine determination

Cytokine levels in cell culture supernatants were determined using the Performance magnetic Fluorokine MAP cytokine multiplex kit (Bio-technique) and a Bioplex 200 machine. The data were analyzed using Bioplex Manager 6.1 software to determine analyte concentrations.

Cell damage assay

Following incubation, culture supernatant was collected and assayed for lactate dehydrogenase (LDH) activity using the Cytotoxicity 96 Non-Radioactive Cytotoxicity Assay kit (Promega) according to the manufacturer's instructions. Recombinant porcine LDH (Sigma-Aldrich) was used to generate a standard curve.

Epithelial adhesion assay

Quantification of *C. albicans* adherence to TR146 epithelial cells was performed as described previously⁴³. Briefly, TR146 cells were grown to confluence on glass coverslips for 48 h in tissue culture plates in DMEM medium. *C. albicans* yeast cells (2×10^5) were added into 1

ml serum-free DMEM, incubated for 60 min (37°C/5% CO₂) and non-adherent *C. albicans* cells removed by aspiration. Following washing (3x 1 ml PBS), cells were fixed with 4% paraformaldehyde (Roth) and adherent *C. albicans* cells stained with Calcofluor White and quantified using fluorescence microscopy. The number of adherent cells was determined by counting 100 high power fields of 200 µm × 200 µm size. Exact total cell numbers were calculated based on the quantified areas and the total size of the cover slip.

Epithelial invasion assay

C. albicans invasion of epithelial cells was determined as described previously⁴³. Briefly, TR146 epithelial cells were grown to confluence on glass coverslips for 48 h and then infected with *C. albicans* yeast cells (1×10⁵), for 3 h in a humidified incubator (37°C/5% CO₂). Following washing (3x PBS), the cells were fixed with 4% paraformaldehyde. All surface adherent fungal cells were stained for 1 h with a rabbit anti-*Candida* antibody and subsequently with a goat anti-rabbit-Alexa Fluor 488 antibody. After rinsing with PBS, epithelial cells were permeabilized (0.1% Triton X-100 in PBS for 15 min) and fungal cells (invading and non-invading) were stained with Calcofluor White. Following rinsing with water, coverslips were visualized using fluorescence microscopy. The percentage of invading *C. albicans* cells was determined by dividing the number of (partially) internalized cells by the total number of adherent cells. At least 100 fungal cells were counted on each coverslip.

Imaging of *C. albicans* growth and invasion of epithelial cells

TR146 cells (10⁵/ml) seeded on glass coverslips in DMEM/10% FBS were infected with *C. albicans* (2.5 × 10⁴ cfu/ml) in DMEM and incubated for 6 h (37°C/5% CO₂). Cells were washed with PBS, fixed overnight (4°C in 4% paraformaldehyde) and stained with Concanavalin A-Alexa Fluor 647 in PBS (10 µg/ml) for 45 min at room temperature in the dark with gentle shaking (70 rpm) to stain the fungal cell wall. Epithelial cells were permeabilised with 0.1% Triton X-100 for 15 min at 37°C in the dark, then washed and stained with 10 µg/ml Calcofluor White (0.1 M Tris-HCl pH 9.5) for 20 min at room temperature in the dark with gentle shaking. Cells were rinsed in water and mounted on slides with 6 µl of ProLong Gold anti-fade reagent, before air drying for 2 h in the dark. Fluorescence microscopy was performed on a Zeiss Axio Observer Z1 microscope, and 5 phase images were taken per picture.

Scanning Electron Microscopy

For scanning electron microscopy (SEM) analysis, TR146 cells were grown to confluence on Transwell inserts (Greiner) and serum starved overnight in serum-free DMEM. After 5 h of *C. albicans* incubation on epithelial cells at an MOI of 0.01, cell media was removed and samples were fixed overnight at 4°C with 2.5% (v/v) glutaraldehyde in 0.05 M HEPES buffer (pH 7.2) and post-fixed in 1% (w/v) osmium tetroxide for 1 h at room temperature. After washing, samples were dehydrated through a graded ethanol series before being critical point dried (Polaron E3000, Quorum Technologies Ltd). Dried samples were mounted using carbon double side sticky discs (TAAB) on aluminium pins (TAAB) and gold coated in an Emitech K550X sputter coater (Quorum Technologies Ltd). Samples were examined and images recorded using a FEI Quanta 200 field emission scanning electron microscope operated at 3.5 kV in high vacuum mode.

Zebrafish swimbladder mucosal infection model

Zebrafish infections were performed in accordance with NIH guidelines under Institutional Animal Care and Use Committee (IACUC) protocol A2009-11-01 at the University of Maine. To determine sample size, a power calculation was done for all experiments based on 2-tails T-test in order to detect a minimum effect size of 0.8, with an alpha error probability of 0.05 and a power (1 – beta error probability) of 0.95. This gave a minimum number of 42 fish for each group. The fish selected for the experiments were randomly assigned to the different groups by picking them from a pool without bias and the groups were injected in different orders. No blinding was used to read the results. Ten to twenty zebrafish per group per experiment were maintained at 33°C in E3 + PTU and used as previously described⁴⁰. Briefly, 4 day post-fertilization (dpf) larvae were treated with 20 µg/ml dexamethasone dissolved in 0.1% DMSO 1 h prior to infection and thereafter. For tissue damage and neutrophil recruitment, individual AB or *mpo:GFP* fish (respectively) were injected into the swimbladder with 4 nl of PBS with/without 25-40 *C. albicans* yeast cells of *ece1Δ/Δ-dTomato*, *ece1Δ/Δ+ECE1-dTomato*, *ece1Δ/Δ+ECE1_{Δ184-279}-dTomato* or BWP17-*dTomato*. For tissue damage, 1 nl of Sytox green (0.05 mM in 1% DMSO) was injected at 20 h post-infection into the swimbladder and fish were imaged by confocal microscopy at 24 h post-infection. For neutrophil recruitment, fish were imaged at 24 h post-injection. For synthetic peptide damage, AB or α -catenin:citrine⁴⁴ fish were injected with 2 nl of peptide (9 ng or 1.25 ng per fish) or vehicle (40% DMSO or 5% DMSO) + SytoxGreen (0.05 mM in 1% DMSO) or SytoxOrange (0.5 mM in 10% DMSO) and the fish imaged by confocal

microscopy 4 h later. Numbers of neutrophils and damaged cells observed were counted and tabulated for each fish.

Zebrafish swimbladder fluorescence microscopy

Live zebrafish imaging was carried out as previously described⁴⁰. Briefly, fish were anesthetized in Tris-buffered Tricaine (200 µg/ml, Western Chemicals) and further immobilized in a solution of 0.4% low-melting-point agarose (LMA, Lonza) in E3 + Tricaine in a 96-well plate glass-bottom imaging dish (Greiner Bio-On). Confocal imaging was carried out using an Olympus IX-81 inverted microscope with an FV-1000 laser scanning confocal system (Olympus). Images were collected and processed using Fluoview (Olympus) and Photoshop (Adobe Systems Inc.). Panels are either a single slice for the differential interference contrast channel (DIC) with maximum projection overlays of fluorescence image channels (red-green), or maximum projection overlays of fluorescence channels. The number of slices for each maximum projection is specified in the legend of individual figures.

Murine oropharyngeal candidiasis model

Murine infections were performed under UK Home Office Project Licence PPL 70/7598 in dedicated animal facilities at King's College London. No statistical method was used to pre-determine sample size. No method of randomization was used to allocate animals to experimental groups. Mice in the same cage were part of the same treatment. The investigators were not blinded during outcome assessment. A previously described murine model of oropharyngeal candidiasis using female Balb/c mice⁴⁵ was modified for investigating early infection events. Briefly, mice were treated sub-cutaneously with 3 mg/mouse (in 200 µl PBS with 0.5% Tween 80) of cortisone acetate on days -1 and 1 post-infection. On day 0, mice were sedated for ~75 min with an intra-peritoneal injection of 110 mg/kg ketamine and 8 mg/kg xylazine, and a swab soaked in a 10⁷ cfu/ml *C. albicans* yeast culture in sterile saline was placed sub-lingually for 75 min. After 2 days, mice were sacrificed, the tongue excised and divided longitudinally in half. One half was weighed, homogenized and cultured to derive quantitative *Candida* counts. The other half was processed for histopathology and immunohistochemistry.

Immunohistochemistry of murine tissue

C. albicans infected murine tongues were fixed in 10% (v/v) formal-saline before being embedded and processed in paraffin wax using standard protocols. For each tongue, 5 μ m sections were prepared using a Leica RM2055 microtome and silane coated slides. Sections were dewaxed using xylene, before *C. albicans* and infiltrating inflammatory cells were visualized by staining using Periodic Acid-Schiff (PAS) stain and counterstaining with haematoxylin. Sections were then examined by light microscopy. Histological quantification of infection was undertaken by measuring the area of infected epithelium and expressed as a percentage relative to the entire epithelial area.

Whole cell patch clamp

TR146 epithelial cells were grown in 35 mm petri dishes (Nunc) for 48 h before recordings at low cell density (10-30% confluence). Cells were superfused with a modified Krebs solution (120 mM NaCl, 3 mM KCl, 2.5 mM CaCl_2 , 1.2 mM MgCl_2 , 22.6 mM NaHCO_2 , 11.1 mM glucose, 5 mM HEPES pH 7.4). Isolated cells were recorded at room temperature (21-23°C) in whole cell mode using microelectrodes (5-7 M Ω) containing 90 mM potassium acetate, 20 mM KCl, 40 mM HEPES, 3 mM EGTA, 3 mM MgCl_2 , 1 mM CaCl_2 (free Ca^{2+} 40 nM), pH 7.4. Cells were voltage clamped at -60 mV using an Axopatch 200A amplifier (Axon Instruments) and current/voltage curves were generated by 1 s steps between -100 to + 50 mV. Treatments were applied to the superfusate to produce the final required concentration, with vehicle controls similarly applied. Data was recorded using Clampex software (PCLamp 6, Axon Instrument) and analyzed with Clampfit 10.

Calcium flux

TR146 cells were grown in a 96-well plate overnight until confluent. The medium was removed and 50 μ l of a Fura-2 solution (5 μ l Fura-2 (Life Technologies)(2.5 mM in 50% Pluronic F-127 (Life technologies):50% DMSO), 5 μ l probenecid (Sigma) in 5 ml saline solution (NaCl (140 mM), KCl (5 mM), MgCl_2 (1 mM), CaCl_2 (2 mM), Glucose (10 mM) and HEPES (10 mM), adjusted to pH 7.4)) was added and the plate incubated for 1 h at 37°C/5% CO_2 . The Fura-2 solution was replaced with 50 μ l saline solution and baseline fluorescence readings (excitation 340 nm/emission 520nm) taken for 10 min using a FlexStation 3 (Molecular Devices). Ece1 peptides were added at different concentrations and readings immediately taken for up to 3 h. The data was analyzed using Softmax Pro software to determine calcium present in the cell cytosol and expressed as the ratio between excitation and emission spectra.

Impedance spectroscopy of tethered bilayer lipid membranes (tBLMs)

tBLMs with 10% tethering lipids and 90% spacer lipids (T10 slides) were formed using the solvent exchange technique^{46,47} according to the manufacturer's instructions (SDx Tethered Membranes Pty Ltd, Sydney, Australia). Briefly, 8 μ l of 3 mM lipid solutions in ethanol were added, incubated for 2 min and then 93.4 μ l buffer (100 mM KCl, 5 mM HEPES, pH 7.0) was added. After rinsing 3x with 100 μ l buffer the conductance and capacitance of the membranes were measured for 20 min before injection of Ece1 peptides at different concentrations. All experiments were performed at room temperature. Signals were measured using the tethaPod (SDx Tethered Membranes Pty Ltd, Sydney, Australia).

FRET intercalation experiments

Intercalation of Ece1 peptides into phospholipid liposomes was determined by FRET spectroscopy applied as a probe-dilution assay⁴⁸. Phospholipids mixed with each 1% (mol/mol) of the donor dye NBD-phosphatidylethanolamine (NBD-PE) and of the acceptor dye rhodamine-PE, were dissolved in chloroform, dried, solubilized in 1 ml buffer (100 mM KCl, 5 mM HEPES, pH 7.0) by vortexing, sonicated with a titan tip (30 W, Branson sonifier, cell disruptor B15), and subjected to three cycles of heating to 60°C and cooling down to 4°C, each for 30 min. Lipid samples were stored at 4°C for at least 12 h before use. Ece1 peptide was added to liposomes and intercalation was monitored as the increase of the quotient between the donor fluorescence intensity I_D at 531 nm and the acceptor intensity I_A at 593 nm (FRET signal) independent of time.

Circular Dichroism spectroscopy

CD measurements were performed using a Jasco J-720 spectropolarimeter (Japan Spectroscopic Co., Japan), calibrated as described previously⁴⁹. CD spectra represent the average of four scans obtained by collecting data at 1 nm intervals with a bandwidth of 2 nm. The measurements were performed in 100 mM KCl, 5 mM HEPES, pH 7.0 at 25°C and 40°C in a 1.0 mm quartz cuvette. The Ece1-III concentration was 15 μ M.

Planar lipid bilayers

Planar lipid bilayers were prepared using the Montal-Mueller technique⁵⁰ as described previously⁵¹. All measurements were performed in 5 mM HEPES, 100 mM KCl, pH 7.0 (specific electrical conductivity 17.2 mS/cm) at 37°C.

Hyphal secretome preparation for LC-MS/MS analysis

Candida strains were cultured for 18 h in hyphae inducing conditions (YNB medium containing 2% sucrose, 75 mM MOPSO buffer pH 7.2, 5 mM N-acetyl-D-glucosamine, 37°C). Hyphal supernatants were collected by filtering through a 0.2 µm PES filter, and peptides were enriched by Solid Phase Extraction (SPE) using first C4 and subsequently C18 columns on the C4 flowthrough. After drying in a vacuum centrifuge, samples were resolubilised in loading solution (0.2% formic acid in 71:27:2 ACN/H₂O/DMSO (v/v/v)) and filtered through a 10 kDa MWCO filter. The filtrate was transferred into HPLC vials and injected into the LC-MS/MS system. LC-MS/MS analysis was carried out on an Ultimate 3000 nano RSLC system coupled to a QExactive Plus mass spectrometer (ThermoFisher Scientific). Peptide separation was performed based on a direct injection setup without peptide trapping using an Accucore C4 column as stationary phase and a column oven temperature of 50°C. The binary mobile phase consisting of A) 0.2% (v/v) formic acid in 95:5 H₂O/DMSO (v/v) and B) 0.2% (v/v) formic acid in 85:10:5 ACN/H₂O/DMSO (v/v/v) was applied for a 60 min gradient elution: 0-1.5 min at 60% B, 35-45 min at 96% B, 45.1-60 min at 60% B. The Nanospray Flex Ion Source (ThermoFisher Scientific) provided with a stainless steel emitter was used to generate positively charged ions at 2.2 kV spray voltage. Precursor ions were measured in full scan mode within a mass range of m/z 300-1600 at a resolution of 70k FWHM using a maximum injection time of 120 ms and an automatic gain control target of 1e6. For data-dependent acquisition, up to 10 most abundant precursor ions per scan cycle with an assigned charge state of z = 2-6 were selected in the quadrupole for further fragmentation using an isolation width of m/z 2.0. Fragment ions were generated in the HCD cell at a normalised collision energy of 30 V using nitrogen gas. Dynamic exclusion of precursor ions was set to 20 s. Fragment ions were monitored at a resolution of 17.5k (FWHM) using a maximum injection time of 120 ms and an AGC target of 2e5.

Protein database search

Thermo raw files were processed by the Proteome Discoverer (PD) software v1.4.0.288 (Thermo). Tandem mass spectra were searched against the *Candida* Genome Database (http://www.candidagenome.org/download/sequence/C_albicans_SC5314/Assembly22/current/C_albicans_SC5314_A22_current_orf_trans_all.fasta.gz; status: 2015/05/03) using the Sequest HT search algorithm. Mass spectra were searched for both unspecific cleavages (no enzyme) and tryptic peptides with up to 4 missed cleavages. The precursor mass tolerance

was set to 10 ppm and the fragment mass tolerance to 0.02 Da. Target Decoy PSM Validator node and a reverse decoy database was used for (qvalue) validation of the peptide spectral matches (PSMs) using a strict target false discovery (FDR) rate of < 1%. Furthermore, we used the Score versus Charge State function of the Sequest engine to filter out insignificant peptide hits (xcorr of 2.0 for z=2, 2.25 for z=3, 2.5 for z=4, 2.75 for z=5, 3.0 for z=6). At least two unique peptides per protein were required for positive protein hits.

Statistics

TransAM and patch clamp data were analyzed using a paired t-test whilst cytokines, LDH and calcium influx data were analyzed using one-way ANOVA with all compared groups passing an equal variance test. Murine *in vivo* data was analyzed using the Mann-Whitney test. Zebrafish data was analyzed using the Kruskal-Wallis test with Dunn's multiple comparison correction. In all cases, $P < 0.05$ was taken to be significant.

<i>bmt6Δ/Δ</i>	Beta-mannosyltransferase	[106]	Hyphae	Yes	Yes	Yes	Yes	[66]
<i>gsc1Δ/GSCI</i>	Beta-1,3-glucan synthase catalytic subunit	[107]	Hyphae	Yes	Yes	Yes	Yes	[66]
<i>gsl1Δ/Δ</i>	Beta-1,3-glucan synthase subunit	[107]	Hyphae	Yes	Yes	Yes	Yes	[66]
<i>gsl2Δ/Δ</i>	Beta-1,3-glucan synthase subunit	[107]	Hyphae	Yes	Yes	Yes	Yes	[66]
<i>kre6Δ/KRE6</i>	Beta-1,6-glucan synthase subunit	[108]	Hyphae	Yes	Yes	Yes	Yes	This study

^{*} Morphology recorded 2 h post-infection on TR146 buccal epithelial cell monolayers; hyphae includes pseudohyphae.

[†] Data based on Western blotting.

[‡] Cytokines includes IL-1α, IL-6 and G-CSF.

[§] Damage measured by LDH assay.

[¶] New *ece1Δ/Δ* also created in this study (See Extended Data Table 2). Original mutant (in red) produced by [27] using the URA-blaster protocol [3]. A set of *ece1* mutants, including partial deletion of *ECE1* and a revertant, was produced in this study in the same genetic background using strain BWP17 to avoid a URA3 effect based on genomic location [109, 110].

[‡] Partial activation is due to lack of adhesion.

Extended Data Table 2. *C. albicans* mutant strains constructed and used in this study.

dTom REV	PCR	aaggctcacttcacctcacc	Confirmation of pENO1-dTom plasmid integration
ACT1-F	qPCR	tcagaccagctgatttaggtttg	Quantification of actin cDNA
ACT1-R	qPCR	gtgaacaatggatggaccag	Quantification of actin cDNA
ECE1-F	qPCR	atcgaataatgccaagagag	Quantification of <i>ECE1</i> cDNA
ECE1-R	qPCR	agcattttcaataccgacag	Quantification of <i>ECE1</i> cDNA
